Microwave-assisted Synthesis of 2-Substituted
4,5,6,7-Tetrahydro-1,3-thiazepines from 4-
Aminobutanol

Abstract

A general procedure for the synthesis of 2-substituted tetrahydro-1,3-thiazepines is presented, by MW-assisted cyclization of 4-thioamidobutanols. The acyclic precursors were prepared in high overall yields by an expeditious three step diacylation/thionation/deprotection sequence from 4-aminobutanol. Microwave assisted ring closure of 4-thioamidoalcohols promoted by trimethylsilyl polyphosphosphate (PPSE) in solvent-free conditions allowed for the synthesis of several hitherto unreported seven-membered iminothioethers bearing 2-aryl, alkenyl, aralkyl and alkyl substituents. The cyclodehydration reaction is likely to involve a $S_N2$-type displacement and affords good to excellent yields of the desired heterocycles in very short reaction times.

Keywords
Introduction

Thiazolines (4,5-dihydrothiazoles) are widely studied heterocycles due to their multiple applications as antibiotics [1], antiproliferative agents [2], anti-inflammatory agents [3] and antithrombotics [4]. They are also found in many bioactive natural products [5], some of which display anti-HIV-1 [6] and antimitotic activities [7], among others. Thiazolines also find use in organic synthesis as building blocks in drug discovery, and as ligands in metal catalyzed reactions [8-13]. Their six membered homologues (5,6-dihydro-4H-1,3-thiazines) are also compounds of broad interest [14], due to their bioactivities [15] and as valuable synthetic intermediates [16].

On the other hand, the seven membered iminothioethers (4,5,6,7-tetrahydro-1,3-thiazepines) have remained almost unexplored. This virtual void is probably due to the known difficulty of the annulation of seven membered heterocyclic rings. In fact, ring closure reactions leading to medium-size heterocycles are hampered by unfavourable entropic and enthalpic factors, and usually characterized by harsh reaction conditions, long reaction times, low yields and/or competitive intermolecular reactions [17].

In 1963, 2-(2,6-dichlorophenyl)-4,5,6,7-tetrahydro-1,3-thiazepine was prepared by a double displacement reaction between 2,6-dichlorothiobenzamide and 1,4-butylenedibromide [18]. In 1970, Mente prepared a dehydro analogue, namely 2-(4-chlorophenyl)-4,7-dihydro-1,3-thiazepine, via thermolysis of N-(4-chlorothiobenzoyl) vinylaziridine [19]. No yields were reported for these reactions in either case. The synthesis of 2-phenyl-4,5,6,7-tetrahydro-1,3-thiazepine by cyclodehydration of N-(4-phenyl-4,5,6,7-tetrahydro-1,3-thiazepine-2-carboxamide) with 30% aqueous formaldehyde in methanol has been described [10]. However, the yield was not reported.
hydroxybutyl)thiobenzamide was attempted with different condensing agents: PPA (100º, 15 h), Burgess (25º, 48 h) and PEG-Burgess (80º, 2 h) reagents, and under Mitsunobu conditions. In the first case, the 1H NMR spectrum of the resulting product contained no signals in the aromatic region [20]. The Burgess reagent led to 58% of the desired product, while the modified PEG-Burgess reagent yielded a mixture of the thiazepine (17%) and the isomeric N-thiobenzoylpyrrolidine (40%). The use of Mitsunobu conditions led exclusively to the pyrrolidine derivative (76%) [21]. Therefore, the few literature examples reported until now are either complicated by side reactions or involve long reaction times and/or modest yields.

Polyphosphoric acid (PPA) esters PPE (ethyl polyphosphate) and PPSE (trimethylsilyl polyphosphate) are powerful and versatile dehydrating agents that find many applications in organic synthesis [22]. Their preparation is operationally simple and requires readily available and inexpensive starting materials. In addition, they are stable, non toxic and environmentally safe. These reagents play a dual role, as they enhance the electrophilicity of nitriles, carbonyls and carbinols, and can also react irreversibly with water. Unlike PPA, a Brönsted acid incompatible with some acid sensitive functionalities, PPE and PPSE are aprotic and mild reagents, with wide functional group tolerance. The use of PPA has some operational disadvantages: it is an extremely viscous liquid that requires high temperatures to allow stirring of the reaction mixture, in which organic compounds do not generally dissolve, while PPA esters are soluble in many organic solvents [23].

Ring closure reactions leading to different heterocyclic cores are relevant among the synthetic applications of PPA esters. The use of MW irradiation as the energy source in these reactions [24] is of particular interest due to the many advantages associated with MAOS: very short reaction times, minimization of side products and consequent
increment of the yields. To our knowledge, however, PPA esters had not been tested yet for the synthesis of cyclic iminothioethers.

As part of an ongoing program on the applicability of PPE and PPSE to the synthesis of nitrogen heterocycles [25], we developed a general method for the preparation of 5 and 6-membered cyclic iminoethers (2-oxazolines and 5,6-dihydro-4H-1,3-oxazines, respectively), by MW-assisted ring closure of amidoalcohols promoted by PPA esters [25g]. PPE and PPSE were then tested for the synthesis of the more challenging seven membered heterocycles, namely 4,5,6,7-tetrahydro-1,3-oxazepines. Instead of the target compounds, the reactions led to the corresponding N-acylpyrrolidines, as disclosed by Hoogenboom et al. [26]. These results were intriguing, since the synthesis of some seven- and even eight-membered 1,3-diheterocycles had already been achieved by our group using the PPA ester/MW system [25a,c,e,f].

Considering the lack of efficient methods for 4,5,6,7-tetrahydro-1,3-thiazepines, we decided to explore their synthesis by microwave-assisted ring closure of N-(4-hydroxybutyl)thioamides promoted by PPA esters. The preparation of these acyclic precursors is not straightforward, as it involves a selective thionation step.

We present herein a novel method for the synthesis of seven membered cyclic iminothioethers from commercially available 4-aminobutanol. The sequence allows the preparation of 4,5,6,7-tetrahydro-1,3-thiazepines bearing 2-aryl, aralkyl, alkenyl and alkyl substituents.

Results and Discussion

Synthesis of the acyclic precursors

As previously mentioned, some difficulties were anticipated regarding the synthesis of 4-thioamidobutanols. In fact, direct thionation of the corresponding 4-
amidoalcohols cannot be used, as the OH is almost as reactive as the amide carbonyl toward Lawesson´s reagent, the most commonly used thionating agent [27]. Two syntheses of ω-thioamidobutanols were recently reported by Nguyen et al. The first one afforded N-thiobenzyloaminobutanol in 62% yield [28], and the second is not applicable to N-thioaroyl derivatives [29]. Thus, a diacylation-thionation-saponification sequence [30] was implemented (Table 1), and the individual steps optimized using 4-aminobutanol and benzoyl chloride as the starting materials.

The diacylation step using pyridine as the base required 24 hs for completion and gave disappointingly low yield due to partial hydrolysis of the ester moiety, while triethylamine performed comparatively better (80%, 24 h). Finally, addition of 10 mol % of DMAP led to a higher yield (95%) in 1h at room temperature. Using the optimized protocol, compounds 1a-k were synthesized in high to excellent yields (Table 1). The more sterically hindered derivatives 1l,m required significantly longer reaction times.

Thionation of the resulting amidoester 1a with Lawesson´s reagent (LR) was then examined. Using the reagent in excess, (LR:substrate=2.5:1, toluene, reflux) the reaction was chemoselective toward the amide group, and compound 2a was obtained in high yield (93%), although the unreacted LR complicated the isolation and purification of the product. Lowering the molar ratio of the starting materials to strictly equivalent 0.5:1 maintained the yield (95%) and considerably simplified the procedure, suppressing collateral products arising from decomposition of the reagent. In these conditions, compounds 2a-m were synthesized in excellent yields (Table 1).

Cleavage of the thioamide-ester 2a with K₂CO₃ in methanol/water (30 min @ 70ºC) afforded thioamidoalcohol 3a (95%). Thioaroyl derivatives 3b-k were prepared in high to quantitative yields under these experimental conditions, except for the more sterically hindered 2-methylphenyl derivative 2h, which required a longer reaction
time (1h) to achieve complete conversion to the desired product. Saponification of the less reactive isobutyryl and pivaloyl derivatives 2l,m required the use of a stronger base, longer reaction times and higher temperature (10% NaOH, reflux, 4 h).

Yields correspond to pure compounds. The reaction was carried out at reflux for 48 h. the reaction was carried out using 10% NaOH:methanol at reflux for 4h

The overall output of the optimized sequence (Table 1, last column) ranged from 69 to 85% for thioaroyl derivatives, and compares favourably with the literature data [28] for 3a (85 vs 62%, respectively). Compounds 3j,l,m afforded slightly lower overall yields.

**Synthesis of tetrahydro-1,3-thiazepines**

With the required precursors in hand, we examined next the MW-assisted heterocyclization of N-thiobenzoylaminobutanol promoted by PPA esters. Using PPE/CHCl₃, irradiation of precursor 3a in a closed vessel MW reactor (1 min @ 90°C) afforded tetrahydrothiazepine 4a in 61% yield. The same reaction was then tested with PPSE/CH₂Cl₂ as the dehydrating agent, leading to poorer results (30% yield). Based on our previous experience on related heterocycles, the cyclization was performed with PPSE in solvent free conditions (8 min @ 90°C), delivering 73% of compound 4a as the only product.

As already mentioned, Wipf *et al.* had previously reported that cyclization of N-thiobenzoylaminobutanol with PEG-linked Burgess reagent and under Mitsunobu conditions led to significant amounts of N-thiobenzoylpyrrolidine [21]. In fact, this kinetically favoured competitive reaction also occurs in the closely related cyclization of N-benzoylaminobutanol with PPSE, which leads exclusively to N-acylpyrrolidines. In order to ascertain the structure of compound 4a, we compared its NMR spectra with those of N-thiobenzoylpyrrolidine (Scheme 1) [31], confirming further the identity of the tetrahydrothiazepine by analysis of its 2D NMR spectra (see SI).
Scheme 1: Chemical shift data for N-thiobenzoypiperidine and compound 4a.

In the optimized experimental conditions, several novel 2-aryl-1,4,5,6-tetrahydro-1,3-thiazepines were synthesized in good to high yields (Table 2). Due to the different reactivity of each substrate, irradiation times and temperatures were individually adjusted by monitoring the disappearance of substrate (TLC). Derivatives 4f-h, bearing ortho-substituted phenyl groups afforded slightly lower yields. Our results compare favourably with the previously reported data (58% yield of 4a, reaction time=48 h) as the method combines the efficiency of PPSE with the advantages of MAOS: very short reaction times and suppression of collateral products.

In view of the encouraging results obtained hitherto, we examined next the applicability of the method to the synthesis of derivatives bearing non-aryl 2-substituents, of which no examples were found in the literature. Previous studies on related cyclic iminoethers [25g] had shown that 2-alkyl derivatives are comparatively more prone to hydrolysis, require harsher reaction conditions and afford significantly lower yields. Despite this, and in order to extend the scope of the method, we attempted the cyclization of some representative examples of this type of substitution. The necessary precursors were prepared by the sequence depicted in Table 1. Regarding the cyclodehydration reaction, in the same experimental
conditions than before (neat PPSE, 1-8 min @ 90°C), thioamidoalcohols 3i-k afforded the corresponding tetrahydro-1,3-thiazepines 4i-k in good to high yields as the only products (Table 2). Ring closure of the more sterically hindered isobutyryl and pivaloyl thioamidoalcohols 3l,m was also successful, requiring slightly higher temperatures.

Mechanistic considerations

The cyclization of 4-amidobutanols promoted by PPA esters leads exclusively to $N$-acylpyrrolidines instead of the corresponding tetrahydro-1,3-oxazepines. This unexpected reaction path is reasonable considering the relative ease of formation of five-membered rings as compared to the isomeric seven-membered heterocycles together with the relatively poor nucleophility of the carboxamide oxygen. An analogous effect was sometimes observed even in the sulphur analogues, as previously mentioned [21]. The differences between oxygen and sulphur regarding electronegativity and polarizability may explain the differential behaviour of the PPSE promoted ring closure of tetramethylenic amido and thioamidoalcohols. In both cases, PPSE would activate the OH group for nucleophilic attack, and the plausible reaction mechanism would involve an intramolecular $S_N2$-type displacement. However, the lower reactivity of the carboxamide oxygen (as an $O$-nucleophile), together with the comparatively high activation energy associated to the formation of a seven-membered heterocycle would favour the competitive ring closure leading to the five-membered ring (Scheme 2, a), which would involve attack of the carboxamide nitrogen to the $\omega$-carbon. On the other hand, the higher nucleophilicity of the sulphur in the thioamide would overcome the difficulty of the formation of the seven-membered ring, yielding exclusively the tetrahydrothiazepine (Scheme 2, b).

Conclusion

We have developed a general method for the synthesis of 2-aryl-tetrahydro-1,3-thiazepines, a heterocyclic core with very few examples in the literature. The method involves as the key step the microwave-assisted ring closure of thioamidoalcohols promoted by PPSE, presumably via an intramolecular S_N2-type displacement of the PPSE-activated OH group. The precursors were easily prepared in a three-step sequence from 4-aminobutanol in high overall yields. The whole synthetic procedure is expeditious and operationally simple, involving inexpensive and readily available starting materials and reagents. The cyclization step affords the desired heterocycles in good to high yields as the only products in a few minutes and is metal, additive and catalyst free. The scope of the method includes the synthesis of unprecedented examples of 2-alkyl, aralkyl and alkenyl derivatives.
